

Antillanca: Yunt scope and purchase orders, version one

Afaq Jamshaid · 7 September 2026 · for review

1. New invoice data arrives by email

Cristian sends new invoice data to a dedicated mailbox. The format we ask for is a ZIP of the SII XML files he already receives, with two folders inside, COMPRAS and VENTAS. Purchases and sales are classified differently and the direction cannot be recovered from the file itself, so it has to come from the folder. If he has data that never existed as XML, we give him a spreadsheet template with fixed columns.

This whole path is ordinary code. An email hook takes the attachment, unpacks it and parses the documents and lines, then runs deterministic checks: the sender is on the allowed list, the size and line count are within limits, and the document is not already stored, matched on issuer RUT plus document type plus folio. Surviving lines go to the classifier endpoint in batches of five hundred. What comes back, three candidate categories with a confidence score and a decision, is written to the database. Confident lines are settled and the rest appear in the review list in the dashboard, exactly as they do today. Cristian gets an acknowledgement within minutes and then a written report of what arrived.

There is no judgement anywhere in that path, so there is no reason to put an agent in it. The Yunt starts where judgement starts.

2. What the Yunt adds on top of a batch

It reviews the batch and flags what looks wrong: line totals that do not match quantity times price, document totals that do not match the sum of their lines, duplicated folios, prices far outside what an item has ever cost, and suppliers never seen before. A flag never changes anything, it is information for a person.

It then proposes categories for the lines the model was unsure about, which is the part with real value. Each proposal carries its evidence, either previously confirmed lines with the same wording or a written convention from Antillanca, and proposals arrive grouped so that approving is one decision rather than fifty. Cristian approves a group, only that group changes, and he gets a written confirmation and an undo.

3. How the open ended questions and reports work

We do not write reports in advance, and the agent does not write queries freely. We enumerate the query space once as a small set of parameterised tools, and the agent only picks a tool and fills in the parameters.

The main tool takes a set of filters (date range, purchases or sales, document type, category, supplier, item, state, amount range), a grouping (by month, category, supplier, document type, item or city), and a measure (sum of amounts, count of lines, count of documents, average unit price, minimum, maximum), plus sorting and a limit. That one tool already answers how much was spent in August, spend by category last quarter, the ten largest suppliers this year, how many lines are still in review, and what a given item has cost over time. Four more tools cover period comparisons, price history for a single item, row level listings that become the spreadsheet attachment, and precedent lookup. Charts come from a fixed set as well: bar, line, stacked bar, pie and table.

The split is the important part. The agent reads the question, picks the tool, fills the parameters, chooses the chart and writes the sentence around the result. The code runs the query, computes every number, builds the table, the spreadsheet and the PDF, and prints the exact filter it used at the top of every answer so Cristian can see whether his question was read correctly. No number in any answer is written by the model.

When a question does not fit the tools, the Yunt says so instead of guessing. That list of refusals is how we learn what to add next, from real questions rather than assumptions. Cristian can also switch on recurring reports: a month end summary, a digest after each batch, and a weekly list of what is still in review.

4. Purchase orders

This part of the dashboard is currently mock up screens with example figures. We make it real, with two forms.

The first form opens a request. Anyone in the company records what they need, how much, by when, and for which farm or cost centre. The item can be something bought before, in which case the Yunt tells them who supplied it and what was paid, or something entirely new, in which case they describe it. The request stays open, and this is how we track what has been asked for but not yet ordered.

Getting quotations is not in the dashboard and there is no way to contact a supplier from it. Whoever is responsible does that however they do it today, by phone, email or in person, and agrees a price.

The second form places the order. It records the supplier, the final agreed price, the quantity and the delivery date. Above 500,000 CLP at least two quotations must be uploaded, which is the rule already shown on their home screen. Below that a formal quotation is not required and the buyer records the price the supplier gave them. The output is a numbered PDF, which Antillanca sends to the supplier themselves. Generating the order closes the request.

The Yunt can do the same by email instead of the dashboard. Cristian says what he needs, the Yunt fills the first form and tells him what the item cost last time and who supplied it. Once a quotation exists it drafts the order and returns the PDF. It will not generate an order while required quotations are missing, and it never contacts a supplier.

5. Left out of version one, deliberately

- **Roles and approval.** The dashboard lists six roles but today they only hide menu items and nothing is enforced. Rules about who may open a request, who may upload quotations and who may approve a purchase belong in version two, once Antillanca tells us who does what and above which amount.
- **Goods receipt, invoice matching and payment.** These need an SII integration and treasury data that we do not have.

Two things we need from Antillanca to finish this: the addresses allowed to send data and receive reports, and confirmation that the 500,000 CLP two quotation rule is what they actually follow. Separately, they offered their own categorised invoices for July and August and nobody collected them. That is the single input that would most improve every category proposal the Yunt makes.
